Abstract

This academic report delves into the landscape of cloud computing, focusing on the comprehensive exploration of cloud service providers and models.

Furthermore, the report examines various cloud models, like Infrastructure as Service (IaaS), Platform as a service (PaaS), Software as a Service (SaaS). The vendors who provide this service are also examined. Through this examination, a critical assignment is made to determine the provider and cloud model for the deployment of a web service.

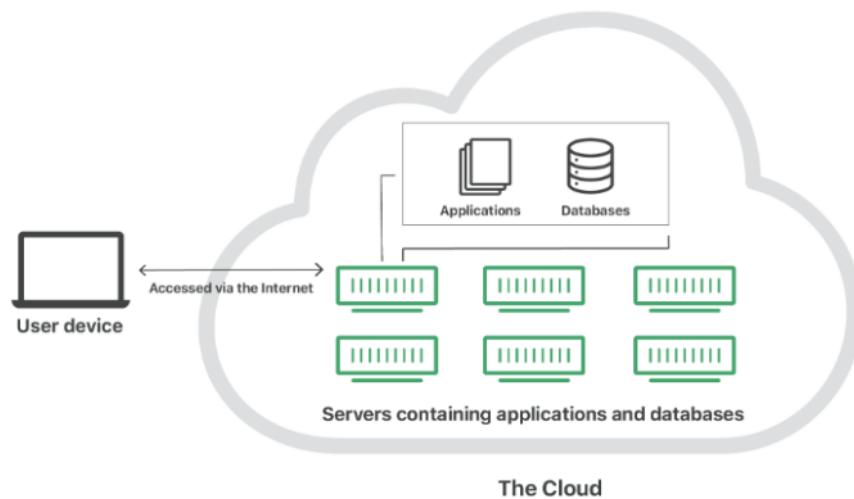

The report concludes with the practical application of this analysis, selecting AWS Elastic Beanstalk as the preferred PaaS offering from Amazon Web Service (AWS) for deploying a web application.

Introduction

The term Cloud, refers to server that are utilized over the internet, and server contains the software and databases. Cloud Computing allows users and companies to be free from responsibility managing physical servers, or even develop the applications on their local machine. To support this, data centers for cloud servers are distributed worldwide (Cloudflare,2023).

The cloud allows the user to connect to a worldwide network, providing access to a changeable set of computing resources like networks, servers, storage, applications, and services. These resources can be utilized by quickly deploying and deactivating with minimal need for management or any sort of interaction with the service provider (Mell & Grance, 2011). The

⁹
cloud computing is defined by its five essential characteristics, three service models and four deployment models (Mell & Grance, 2011).

On demand service:

User can independently and instantly access and manage computing resources without needing direct interaction with the service provider. This feature provides a quick and automated way for the user to get the computer service they require (Bhatia,2023).

Broad network access:

User can access cloud services over the network and with wide range of devices like smart phones, laptop and desktop computers. Cloud service is easily accessible from different locations and through different means, providing flexibility and convenience for user to connect to the cloud. The quality of the service is dependent on the latency and bandwidth of the network (Bhatia,2023).

Resource pooling:

The computer resources like processing power, memory, storage and bandwidth, are aggregated into a common pool that can be used by multiple users or application as needed. It allows for more efficient utilization, as the resources are dynamically allocated and reassigned based on demand. It enables a flexible and cost-effective approach to managing computing resources, ensuring that they are used efficiently across multiple tasks or users rather than dedicated to a single purpose (Bhatia,2023).

Rapid elasticity:

Users can rapidly and easily expand or shrink their usage of resources like processing power, storage, or bandwidth. It provides service which can accommodate a sudden increase in demand during busy period and scale down during quitter time which ensures that necessary resources are available when needed and aren't paying for unused resources (Bhatia,2023).

Measured Service:

The usage of computing resources can be tracked and metered. Cloud provides services to monitor, measure and record how much services user consumes. This allows for the transparent and accountable usage of resources (Bhatia,2023)

These essential characteristics collectively define the fundamental attributes of cloud computing, enabling a scalable, flexible, and efficient approach to services. The subsequent section of the report explores service models and the deployment models.

Literature Review

Cloud vs on premise

Cloud computing involves delivering computing services via the internet rather than relying on local servers or personal computers. On the other hand, on-premises refers to the traditional approach of hosting and managing computing resources within an organization's own physical data center (Team Cleo, 2023).

Differences:

Deployment:

On-Premises: The application or resources are deployed within the server of the company, the company need to buy a server and the organization needs to maintain the application. (Team Cleo, 2023).

Cloud: Resources are hosted by a cloud provider, and the company can simply access and use them as needed without every needing to manage the infrastructure under the hood. (Team Cleo, 2023).

Cost:

On-Premises: As Organizations are the one who have the server so if they want to expand it or have regular maintenance, they need to bear the costs of that server, the cost is also generated by the hardware, power consumption, and space (Team Cleo, 2023).

Cloud: Costs in the cloud computing model are based on usage, and organizations only pay for the resources consumed, without additional maintenance and upkeep expenses. Prices can adjust based on usage (Team Cleo, 2023).

Control:

On-Premises: Enterprises retain full control over their data, making it ideal for companies in highly regulated industries with privacy concerns (Team Cleo, 2023).

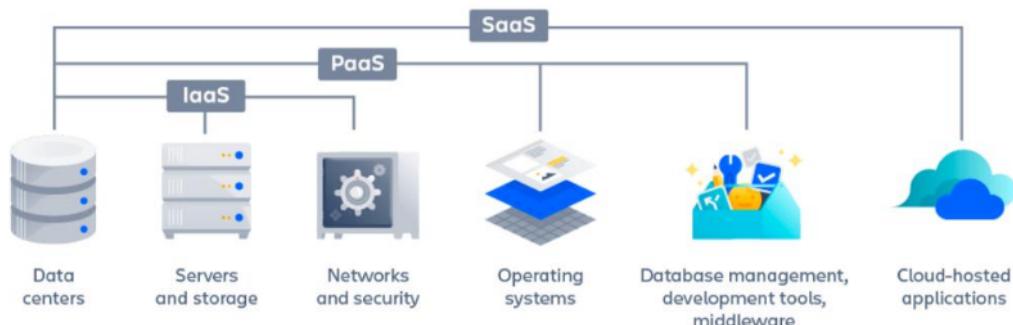

Cloud: The ownership of data in the cloud is a challenge, as data and the encryption keys for the server are with the cloud provider. In case of downtime, accessing data may

become challenging. This aspect can be a concern for some companies and vendors (Team Cleo, 2023).

These are the differences between cloud and on premise.

Cloud Services and their types

In cloud computing there are divided into three main models i.e. IaaS, PaaS, SaaS. These models are divided according to the different level of control, responsibility, management, use-case, security, flexibility and scalability they provide (Kumar, 2023).

2 Infrastructure as a Service (IaaS):

In this type of model, the cloud provider rents the raw hardware resources such as storage, server and networking resources. User can get this resource on internet using pay-as-per use model. This model eliminates the need for every organization to maintain the IT infrastructure. Here, the cloud service provider maintains and manages the hardware so user can only focus on installing, configuring and managing software (GoogleCloud, 2023).

Types of IaaS:

Private Cloud:

It covers the infrastructure located on the customer's premises. Examples: On-premise Data Centers, Dedicated Private Cloud Providers (The IoT Academy, 2023).

Public Cloud:

The cloud situated in data center of the company that provides the cloud computing platform.

Examples of such clouds are: Microsoft Azure, Google Cloud Platform, Amazon Web Service (AWS) (The IoT Academy, 2023).

Hybrid Cloud:

Combines two by allowing user to choose the best feature of each. Example: VMware Cloud on AWS, Azure Hybrid Cloud, Google Anthos (The IoT Academy, 2023).

Benefits:

Economical:

The enterprise will pay for the model they are using and they need to pay based on the resource used and additional they only need to pay for the resource like networking, compute and storage (GoogleCloud, 2023).

Reliable:

Cloud providers have many data centers over the world and they have backup for every machine so even if any component of the hardware resource fails, the service will not be affected (GoogleCloud, 2023).

More innovation:

The deployment becomes easy in cloud, due to which the team don't need to spend weeks and months configuring servers to run application, they can easily deploy the application using cloud and instead can spend that time on the application to make it better (GoogleCloud, 2023).

11

These are the benefits of Infrastructure as a Service (IaaS).

What Is IaaS Made Of?

Platform as a Service (PaaS)

In PaaS, the raw hardware resource is provided with addition of software resources.

Now, user don't need to install any run time environment for the application. This will help the user to develop, run and manage business application without maintain the infrastructure (Kanade, 2022). In this model, the user will not interact with the operating infrastructure, they are managed by the Cloud Service Provider.

Types of PaaS:

8

Some of the types of PaaS are: Public PaaS, Private PaaS, Hybrid PaaS, Communication

PaaS, Mobile PaaS, Mobile PaaS, Open PaaS, iPaaS, MWaaS are types of PaaS (Trad, 2023).

Benefits:

Cost effective:

As the hardware is provided the user doesn't need to invest in those hardware and similarly the OS and other software are also already there as a package, Developers can simply focus on working on the code without needing to worry about servers, development tools etc. (Smact Works, 2019).

Maintenance:

The service provided by cloud provider has automated security patches and updates which ensures that application operates on the recent version and there are no security vulnerabilities. It removes the need of specialist team to maintain environment daily(Smact Works, 2019).

These are the benefits of ² Platform as a Service (PaaS).

Software as a Service (SaaS):

It makes **it** possible for the **users** to connect to and use **cloud-based application** over the network (Microsoft Azure, 2023). It provides complete software that can be purchase on **subscription based** from any **cloud service provider**. All of the **underlying infrastructure**, **middleware**, **app software** and **app data** are managed by providers. It **allows an enterprise to get quickly and work with an app at low cost** (Microsoft Azure, 2023).

Benefits:

Usage Based Pricing:

The service automatically scales up or down depending on the number of user using the service (Microsoft Azure, 2023).

Freeware:

This service is already built and user only need to use it through the help of web browser, they don't need to configure or install any other software (Microsoft Azure, 2023).

Mobilize workforce effortlessly:

SaaS, makes it easy for the users to access applications from anywhere through the internet. There is no any problem in running the application on any type of computer as that is already provided as a service (Microsoft Azure, 2023).

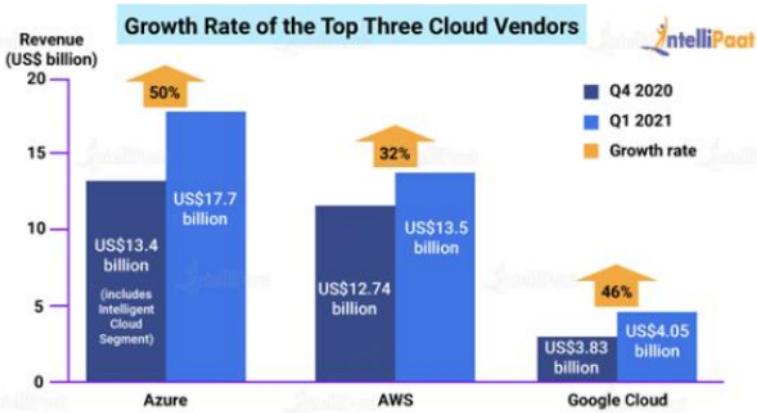

16
These are the benefits of Software as a Service (SaaS).

Cloud vendors

There are many cloud vendors globally and among them top 10 are ranked with their regions and availability zones.

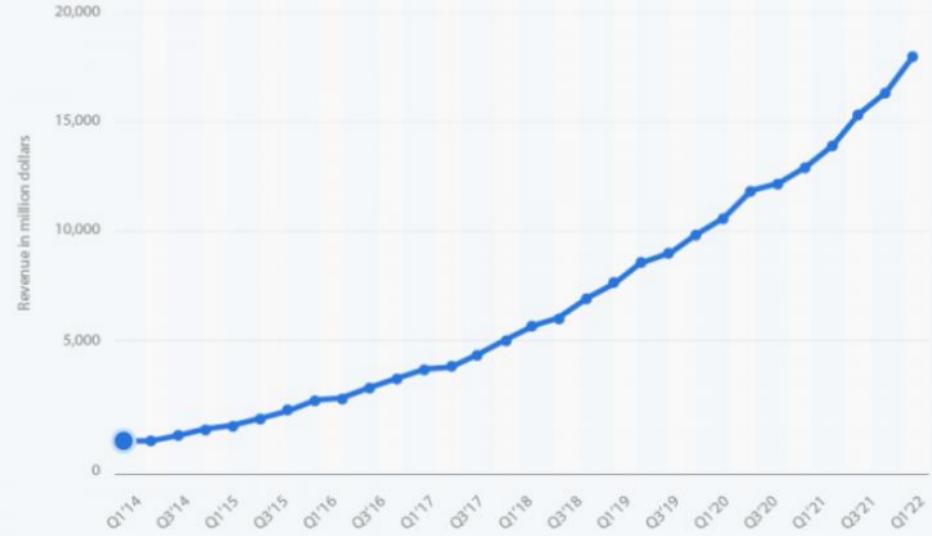

#	Cloud Service Provider	Regions	Availability Zones
1	Amazon Web Services (AWS)	32	102
2	Microsoft Azure	62	120
3	Google Cloud Platform (GCP)	39	118
4	Alibaba Cloud	30	89
5	Oracle Cloud	46	56
6	IBM Cloud (Kyndryl)	10	30
7	Tencent Cloud	21	65
8	OVHcloud	17	37
9	DigitalOcean	9	15
10	Linode (Akamai)	20	20

Amazon Web Services (AWS):

AWS stands out as one of the leading global cloud service providers, boasting a range of over 200 fully featured services delivered from its data centers (Zhang, 2023). At present, it operates in 32 regions and 102 availability zones, positioned across the world in areas of United States, Americas, Europe, Asia Pacific, Middle East and Africa (Zhang, 2023).

AWS market share: AWS revenue

During ten years, AWS has a steep rise and its market share has increased more than 10 times.

From the initial \$4.6 billion in 2014 to over \$18 billion in 2022, The market share has grown massively as the revenue (Rahul, 2023). It been forecasted that IaaS is expected to witness substantial increase in end-user spending, with growths by 30.6%. In comparison DaaS will grow by 26.6% and PaaS by 26.1% (Rahul, 2023).

	2021	2022	2023
Cloud Business Process Services(BPaaS)	51,410	55,598	60,619
Cloud Application Infrastructure Services(PaaS)	86,943	109,623	136,404
Cloud Application Services(SaaS)	152,184	176,622	208,080
Cloud Management and Security Services	26,665	30,471	35,218
Cloud System Infrastructure Services(IaaS)	91,642	119,717	156,276
Desktop as a Service(DaaS)	2,072	2,623	3,244
Total Market	410,915	494,654	599,840

BPaaS = business process as a service; IaaS = infrastructure as a service; PaaS = Platform as a service; SaaS = Software as a Service.
 NOTE: Total may not add up due to rounding.

Worldwide Public Cloud Services End-User Spending Forecast (Millions of U.S. Dollars) : Gartner

AWS is used by: Coursera, Intuit, Expedia, Airbnb, Netflix, Lyft, Coinbase, Coca Cola (Coursera, 2023)

Microsoft Azure:

As the second largest cloud service provider worldwide, it ensures a consistent hybrid cloud experience, boost developer productivity, offers artificial intelligence capabilities and prioritizes security & compliance (Zhang, 2023). With 62 regions and 120 availability zones, these services are distributed across the US, Americas, Europe, Asia Pacific, Middle East and Africa (Zhang, 2023).

In 2023 its market share is 23%, it increased by 2% from 2022, Microsoft doesn't provide its azure sales figures instead it combines with other services under its Microsoft intelligent Cloud Umbrella (Haranas, 2023). This group generated \$24.3 billion in sales.

Microsoft Azure is used by: Audi, ASOS, HSBC, Starbucks, FedEx, Walmart (Coursera, 2023).

Google Cloud Platform:

Google Cloud Platform holds the third largest global cloud service provider. It offers cloud service tailored for enterprises (Zhang, 2023). It empowers developers to create, test and launch application on its infrastructure, additionally user can also utilize its feature in security, data management, analytics, and AI (Zhang, 2023). This platform spans 39 regions and 118 availability zone, across the US, Americas, Europe, Asia Pacific, Middle East and Africa (Zhang, 2023).

Similarly, for **google cloud**, its market share has remained stable in 11% from 2022 to 2023,

Google cloud is experiencing rapid sales growth, with a year-over-year revenue increase of 22%.

In 2023, the total revenue generated by it reached \$8.4 billion (Haranas, 2023).

Google Cloud Platform is used by: Toyota, Equifax, Nintendo, Spotify, Twitter, PayPal (Coursera, 2023).

Critical Review

Amazon Web Services (AWS) is best at providing the infrastructure service which includes

¹² scalable storage, networking, server, mobile development and cybersecurity solutions

(Coursera, 2023). Microsoft Azure offers one ⁶ of the best scalable and efficient software solution

while Google Cloud Platform (GCP) specializes in advanced big data analytics solutions and

facilitates seamless integration with products from other cloud vendor (Coursera, 2023).

³ AWS vs. Azure vs. Google Cloud: the key difference

In figure 1, basic differences are shown,

Features	Amazon	Microsoft Azure	Google Cloud
Age	11 years old	5 years old	6 years old
Pricing	Per second pricing with a 60-second minimum	Per-minute basis	Per-minute basis
Compute	EC2 (Elastic Compute Cloud) provides all the computing administration. The program oversees virtual machines, which can either be designed by the owner or have pre-configured settings for convenience	With Microsoft Azure, you can create virtual machines and scale sets for virtual machines.	As part of GCP (Google Cloud Platform), GCE (Google Compute Engine) does a similar function.
Storage	AWS provides apportioned, transient (brief) stockpiling. As soon as an instance begins, it is demolished at the end of the case.	Azure uses ID drives (transient capacity), and Page Blobs VM-based volumes are stored in Block Storage (Microsoft's choice). Object Storage uses Square Blobs and Files.	Comparatively, Google's Cloud Platform offers both brief stockpiling and constant circles. For Object stockpiling, GCP has Google Cloud Storage.

Figure:1

AWS entered the public domain in 2006, introducing services like EC2 and Amazon S3. As being one of the early cloud businesses, it has an extensive user base and great trust and reliability (Coursera, 2023). Google cloud launched in 2008, and it has solidified its position in cloud business. Microsoft Azure established in 2010 to offer enterprise with robust cloud computing platform (Coursera, 2023). When choosing a cloud provider, user should consider the regions and availability as things like latency, compliance regulation and data which can have direct influence on cloud.

In figure 2, Each platform computational capabilities individually are shown,

SERVICE	AWS	AZURE	GCP
VM (Compute Instance)	EC2 (Elastic Compute)	Azure Virtual Machine	Google Compute Engine
PaaS	AWS Elastic Beanstalk	App Service	Google App Engine
Container	AWS Elastic Container/Kubernetes Service	Azure Kubernetes Service (AKS)	Google Kubernetes Engine
Serverless Functions	AWS Lambda	Azure Function	Google Cloud Functions

Figure: 2

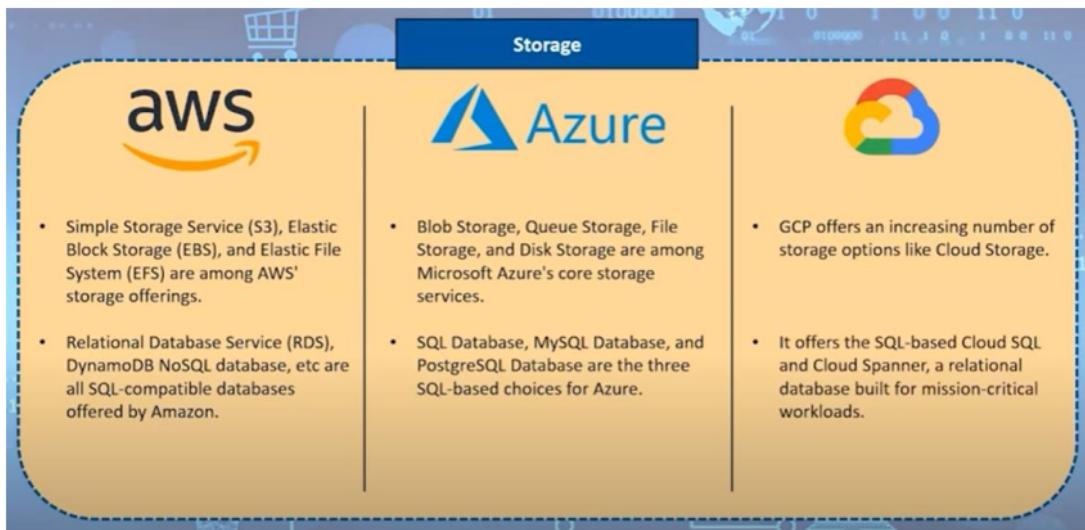

Compute describes how computers works, and is one of the important factors, when looking into these three-cloud provider (Coursera, 2023).

In figure 3, the pricing structure are shown based on machine type each provide,

Machine Type	AWS	Azure	GCP
Smallest Instance	AWS charges roughly US\$69 per month for a primary instance with two virtual CPUs and eight gigabytes of RAM.	In Azure, the same type of instance, i.e., an instance with 2 CPUs and 8 GB of RAM, will cost roughly US\$70 per month.	Compared to AWS, GCP will supply you with the most basic instance, including two virtual CPUs and eight gigabytes of RAM, at a 25% lower cost. As a result, it will cost you around US\$52 every month.
Largest Instance	The most expensive AWS instance, with 3.84 TB of RAM and 128 CPUs, will cost you roughly US\$3.97/hour.	Azure's largest instance includes 3.89 TB of RAM and 128 CPUs. It costs about \$6.79 per hour.	GCP leads the pack with its largest instance, 3.75 TB of RAM and 160 CPUs. It will cost you approximately US\$5.32/hour.

Figure: 3

The general consensus within the community is that Microsoft Azure offers the lowest on-demand cost, Amazon positioned in the middle. These three systems provide user with price plans and extra cost control feature which are largely influenced by customer specification, usage and the service utilized (Coursera, 2023).

Here all this figure shows the difference in cloud services and when a enterprise or user want to use any cloud service, they need to look at their requirement before choosing the cloud service.

For example,

If an enterprise wants to build an ecommerce web application, they can choose AWS to host it, using services like EC2 for computing power, S3 for storing images and files and RDS for managing the relational database. The diverse and scalable services of AWS will help this site to handle traffic holds which will make good experience for customer.

If an enterprise wants to perform advance analytics and use machine learning models on huge data sets then Google Cloud will provide services like Big Query to analyze these datasets quickly and efficiently. Its strength in data analytics and ML makes it the best choice for deriving insight from large datasets.

If an enterprise wants to go from on premise to cloud then Microsoft azure is the best option, as it offers hybrid cloud and robust integration capabilities. Azure virtual machines can be used to extend the on-premise servers to cloud. Its emphasis on integration makes it best choice to companies having complex IT system.

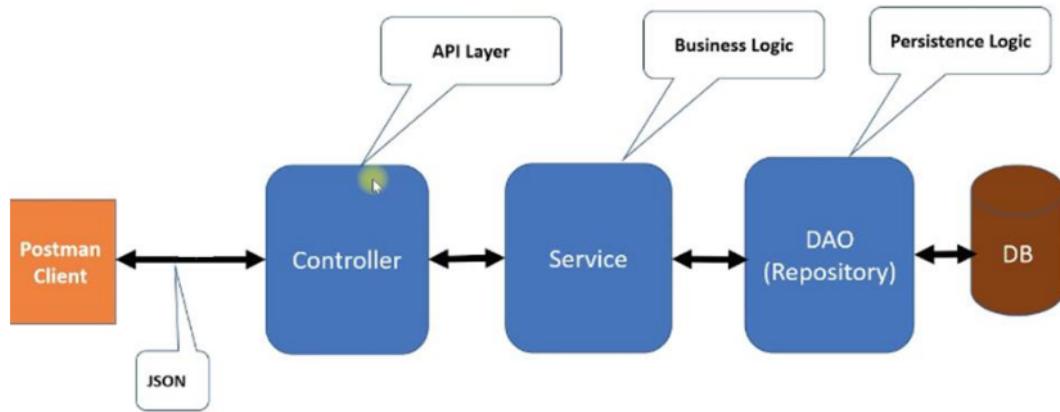

Specification

In this report, the web service was deployed in AWS Elastic Beanstalk, so the used Cloud Provider is AWS while the service is Elastic Beanstalk. The reason to select AWS as service provider is due to its availability, even though it is complex due to many services as AWS is one of the first cloud business there are lots of material like tutorial and reports online to take reference from and learn. AWS also provides me with the facility of automatically scaling my application up if number of user increase while scale down of number of user decrease.

Elastic Beanstalk was used as service because, configuring elastic beanstalk is easy. The application can be developed in local machine and creating a jar file or a zip file, the application can be easily deployed. If there was change in application, simply the application can be uploaded and deployed again causing the version change. It also doesn't waste any time in undifferentiated heavy lifting and doesn't consume lot of time and as this project is simple project so, Elastic Beanstalk was used.

Development and Deployment

Development

This is spring boot application architecture, here we have a controller, who has API layers, service, who has Business Logic and DAO which has persistence logic and a PostgreSQL DB. Here user can access the URL and either add product, see the products, delete the product, add the product to cart or remove the product from cart. There is a local client to run these but the local client is not deployed so Postman is used for testing to check if it is working.

The API is hit using postman and we can see the API return data in form of Json.

14
In this web application there is a local client side, server side and a database. The local client is not deployed while server and database are deployed. Testing of API is done using postman.

The screenshot shows a web browser window with the URL `localhost:5173/add-product`. The page title is "FURNITURE". The main content is an "Add Product" form. The "Product Name" field contains "Mat" and the "Product Price" field contains "75". A blue "Submit" button is visible. Below the form, a message "Product Added" is displayed. The browser's address bar and various icons are visible at the top.

Server Side:

Server Side was created using spring boot. Uses dependency like data jpa, spring web, Lombok and PostgreSQL driver, here only some portions of pics are shown. Server side has 3 entities, Product, Cart and a linked entity cart-item. It has controller, service, repository and model for all this entity. The service contains crud operation for all three entities.

Spring boot was used because of the ability to manage dependency easily. Able to create a secure API,

Easy to make server side as it has less configuration which save a lot of time.

Deployment

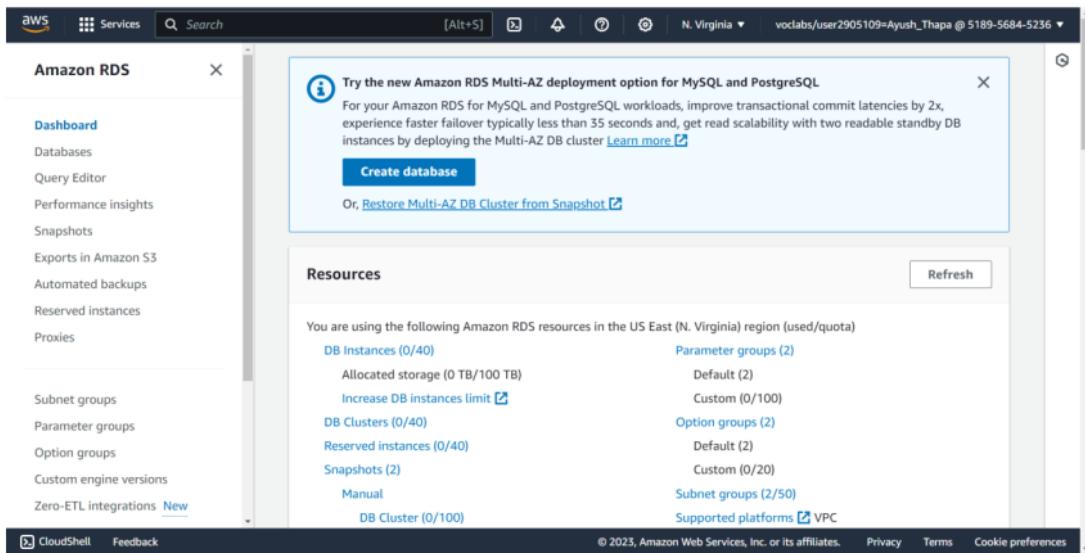

Here, default VPC was used and in the public subnet of the VPC, a RDS service and Elastic Beanstalk service was created. Here the application in deployed in elastic beanstalk is connected to RDS and there is two-way communication between them.

Developmental Step of RDS:

- 1) Find RDS Service

2) Create Database

3) Standard create option

Screenshot of the AWS RDS 'Create database' page for PostgreSQL.

The 'Choose a database creation method' section shows 'Standard create' selected (radio button is blue). The description states: "You set all of the configuration options, including ones for availability, security, backups, and maintenance."

The 'Engine options' section shows 'Engine type' set to 'Info'. It lists several engine types with icons:

- Aurora (MySQL Compatible)
- Aurora (PostgreSQL Compatible)
- MySQL
- MariaDB
- PostgreSQL (radio button is blue, highlighted with a light blue border)
- Oracle
- Microsoft SQL Server
- IBM Db2

The right panel displays detailed information about PostgreSQL, including its features and benefits:

- PostgreSQL is a powerful, open-source object-relational database system with a strong reputation of reliability, stability, and correctness.
- High reliability and stability in a variety of workloads.
- Advanced features to perform in high-volume environments.
- Vibrant open-source community that releases new features multiple times per year.
- Supports multiple extensions that add even more functionality to the database.
- Supports up to 15 Read Replicas per instance, within a single Region or 5 read

5) Free Tier

The screenshot shows the AWS RDS 'Templates' section for PostgreSQL. It displays three options: 'Production', 'Dev/Test', and 'Free tier'. The 'Free tier' option is selected, highlighted with a blue border. A tooltip for 'Free tier' states: 'Use RDS Free Tier to develop new applications, test existing applications, or gain hands-on experience with Amazon RDS.' To the right, a detailed description of PostgreSQL is provided, mentioning its features like high reliability, advanced features, and support for multiple extensions.

PostgreSQL

PostgreSQL is a powerful, open-source object-relational database system with a strong reputation of reliability, stability, and correctness.

- High reliability and stability in a variety of workloads.
- Advanced features to perform in high-volume environments.
- Vibrant open-source community that releases new features multiple times per year.
- Supports multiple extensions that add even more functionality to the database.
- Supports up to 15 Read Replicas per instance, within a single Region or 5 read

6) DB name and username

The screenshot shows the 'Settings' page for a PostgreSQL DB instance. It includes fields for the 'DB instance identifier' (set to 'database-2') and 'Master username' (set to 'postgres'). A note at the bottom indicates that managing master credentials in Secrets Manager will disable some RDS features. The right side of the screen displays the same PostgreSQL description and features as the previous screenshot.

Settings

DB instance identifier [Info](#)
Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

▼ Credentials Settings

Master username [Info](#)
Type a login ID for the master user of your DB instance.

1 to 16 alphanumeric characters. The first character must be a letter.

Manage master credentials in AWS Secrets Manager
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

If you manage the master user credentials in Secrets Manager, some RDS features aren't supported.

7) DB Master password

The screenshot shows the AWS RDS PostgreSQL configuration page. On the left, there's a note about managing master user credentials in Secrets Manager. Below it, there are fields for generating or specifying a master password, with constraints noted: at least 8 printable ASCII characters, no slashes, single quotes, double quotes, or '@' symbols. The 'Master password' field contains '*****'. To its right is a 'Confirm master password' field also containing '*****'. A red 'e' icon is present in both fields. On the right side, a sidebar titled 'PostgreSQL' provides an overview of the database engine, highlighting its reliability, advanced features, vibrant open-source community, and support for multiple extensions. It also mentions supports up to 15 Read Replicas per instance.

8) Using default VPC and public subnet

The screenshot shows the AWS RDS PostgreSQL configuration page under the 'Connectivity' tab. It includes sections for 'Compute resource' (with options for 'Don't connect to an EC2 compute resource' or 'Connect to an EC2 compute resource'), 'Virtual private cloud (VPC)' (with a dropdown set to 'Default VPC (vpc-0c7ced42a847e92ad)', showing 6 Subnets and 6 Availability Zones), and 'DB subnet group' (set to 'default-vpc-0c7ced42a847e92ad', showing 6 Subnets and 6 Availability Zones). A note states that after a database is created, its VPC cannot be changed. On the right, a sidebar titled 'PostgreSQL' provides an overview of the database engine, highlighting its reliability, advanced features, vibrant open-source community, and support for multiple extensions. It also mentions supports up to 15 Read Replicas per instance.

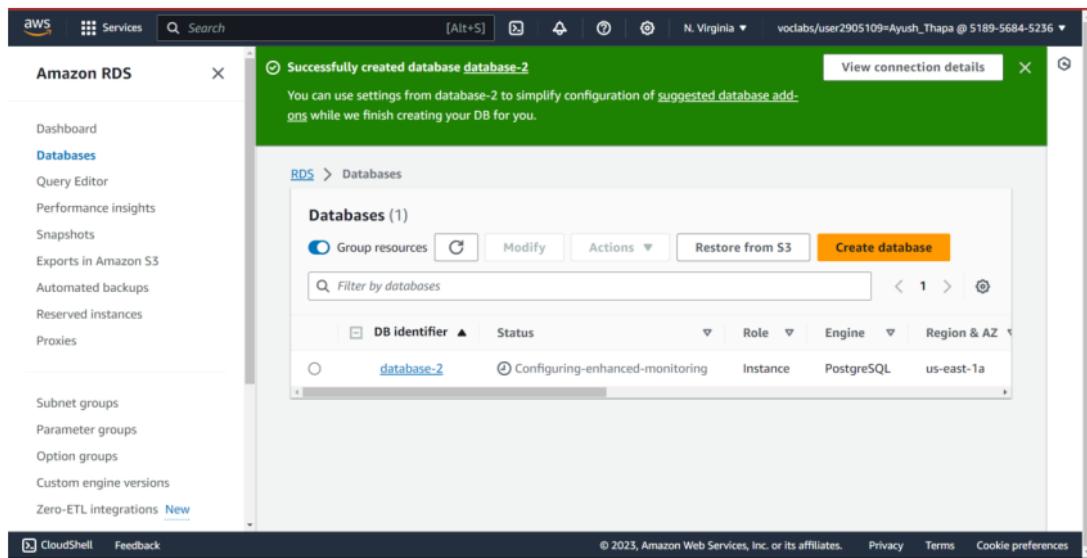

9) Turn on public access

The screenshot shows the AWS RDS PostgreSQL setup wizard. On the left, there's a sidebar with 'Public access' (Info) and two radio button options: 'Yes' (selected) and 'No'. The 'Yes' option is described as assigning a public IP address to the database, allowing Amazon EC2 instances and other resources outside the VPC to connect. The 'No' option is described as not assigning a public IP, allowing only Amazon EC2 instances and other resources inside the VPC to connect. Below this is a 'VPC security group (firewall)' section with 'Info' and two radio button options: 'Choose existing' (selected) and 'Create new'. The 'Choose existing' option is described as choosing one or more VPC security groups to allow access to your database. The 'Create new' option is described as creating a new VPC security group. There are also sections for 'Existing VPC security groups' (with a dropdown menu showing 'Choose one or more options' and a 'default' entry), 'Availability Zone' (Info, with 'No preference' selected), and 'RDS Proxy' (Info, with 'No preference' selected). On the right, a detailed description of PostgreSQL is provided, listing its features: High reliability and stability in a variety of workloads, Advanced features to perform in high-volume environments, Vibrant open-source community that releases new features multiple times per year, Supports multiple extensions that add even more functionality to the database, and Supports up to 15 Read Replicas per instance, within a single Region or 5 read.

10) Creating Database

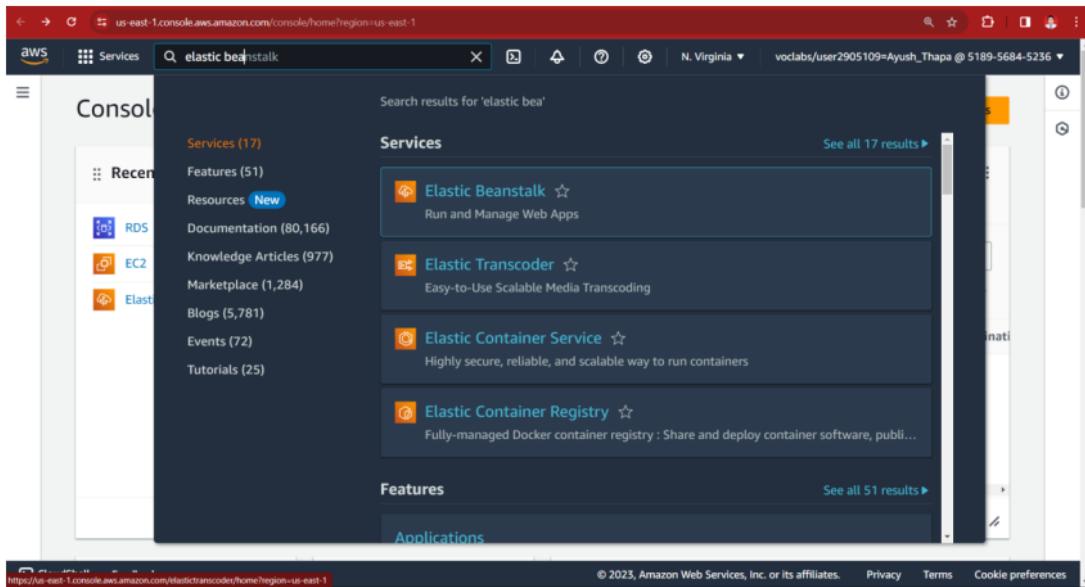

The screenshot shows the AWS RDS Databases page. On the left, there's a sidebar with 'Amazon RDS' and several options: Dashboard, Databases (selected), Query Editor, Performance insights, Snapshots, Exports in Amazon S3, Automated backups, Reserved instances, Proxies, Subnet groups, Parameter groups, Option groups, Custom engine versions, Zero-ETL integrations (New), and CloudShell Feedback. The main area shows a message 'Creating database database-2' with a progress bar indicating the database might take a few minutes to launch. It also says you can use settings from database-2 to simplify configuration of suggested database add-ons while we finish creating your DB for you. A callout box suggests creating a Blue/Green Deployment to minimize downtime during upgrades. The 'Databases (1)' table lists the database 'database-2' with details: Status (Creating), Role (Instance), Engine (PostgreSQL), Region & AZ (us-east-1a), and Size (db.t3.micro). There are buttons for Group resources, Modify, Actions, Restore from S3, and Create database. A 'Filter by databases' search bar is at the top of the table.

Testing:

Testing using Postman

The screenshot shows the Postman application interface. At the top, there is a header bar with the URL "GET http://furniture-app-er" and a status indicator showing a red error icon. Below the header is a search bar containing the URL "http://furniture-app-env.eba-ahem29xg.us-east-1.elasticbeanstalk.com/get-all-products". To the right of the search bar are buttons for "Save", "Send", and "Copy". The main workspace is titled "Params" and contains a table for "Query Params". The table has columns for "Key", "Value", "Description", and "Bulk Edit". There is one row with the key "Key" and value "Value". Below this table, there are tabs for "Body", "Cookies", "Headers (8)", and "Test Results". The "Body" tab is selected and displays a JSON response. The response is shown in a "Pretty" format with line numbers from 1 to 12. The JSON data is as follows:

```
1 [  
2   [  
3     {  
4       "productId": 2,  
5       "productName": "Table",

10      "productName": "Chair",  
11      "productPrice": 50.0  
12   ]]
```

At the bottom of the interface, there are several status indicators: "Status: 200 OK", "Time: 355 ms", and "Size: 362 B". To the right of these are buttons for "Save as Example", "Runner", "Capture requests", "Cookies", "Trash", and a help icon.

The screenshot shows the Postman application interface. A POST request is being made to `http://furniture-app-e`. The URL in the header is `http://furniture-app-env.eba-ahem29xg.us-east-1.elasticbeanstalk.com/add-product`. The request body contains the following JSON:

```
1 {"productId": 4,  
2 "productName": "Bed",  
3 "productPrice": "100"

Conclusion and Reflection

In conclusion, our exploration of cloud versus on-premise solutions has shed light on the dynamic landscape of modern computing. ¹⁸ The advantages of cloud services, including flexibility, scalability, and cost-effectiveness, present compelling reasons for businesses to consider migrating from traditional on-premise infrastructure. While cloud solutions offer unprecedented opportunities for innovation and growth, it's essential to recognize that on-premise solutions still hold value, particularly for organizations with stringent security and compliance requirements.

Our examination of various cloud service models and types has underscored the importance of choosing the right approach based on specific business needs. Whether opting for IaaS, PaaS, or SaaS, organizations must carefully assess their requirements to make informed decisions that align with their goals and objectives.

Furthermore, our exploration of leading cloud vendors, such as AWS, Azure, and Google Cloud, emphasizes the significance of selecting a provider that aligns with the unique demands of a project. Each vendor offers a diverse set of services and features, and understanding their strengths and weaknesses is crucial for successful cloud adoption.

The practical demonstration of developing and deploying a web application on AWS Elastic Beanstalk has showcased the efficiency and simplicity of cloud-based development platforms.

While challenges may arise during the deployment process, the overall experience underscores the potential for streamlined, scalable, and cost-effective application hosting.

Completing this project, learned how to create AWS service, especially RDS and Elastic Beanstalk, how to connect a RDS to server-side application and how to connect server-side application with client application. Technology like postman was learned. This has established a basic understanding of how a application is deployed in cloud and what its advantages are.
